

Phase 8 – Project Demonstration

Conclusion

The Script-Controlled ACL – Restrict Record Access Based on Field Value project was successfully completed using the ServiceNow platform. The project demonstrated how Access Control Lists (ACLs) can be used to secure records by combining user roles with the Branch field value. A custom Institution Details table was created, and users, roles, and Read, Create, Write, and Delete ACLs were configured to enforce role-based access.

The testing results confirmed that users with the appropriate roles could perform only their permitted operations, while administrators retained full access to all records. This project improved our understanding of role-based security, record-level access control, ACL scripting, and ServiceNow application development, providing practical experience in implementing secure access management
